Maxillary first premolar with three roots: Case report

Fausto Rodrigo VICTORINO¹
Christine MEN-MARTINS²

ABSTRACT

Introduction: The maxillary first premolar may rarely present with three roots, two buccal and one palatal, demanding more attention during endodontic intervention. Objective: This paper reports the case of a maxillary first premolar with three roots and three root canals, highlighting the difficulties and special care during endodontic treatment. Methods: After initial radiography and coronal opening, the presence of three roots and three root canals was detected. The exploration of the canals was performed with #10 K-file and the root canal length was measured by means of radiographic technique, which made it possible to confirm the anatomical variation and to assure that the buccal canals were independent. The instrumentation was mixed, with K-type hand files, until #35 file, automatized with Pro-Taper® system (Dentsply). The filling of the canals was performed with the lateral compaction technique with sealer Sealer 26®. Conclusion: Professionals should always carefully consider the diagnostic radiograph and perform all steps of root canal treatment properly, so that possible changes can be detected, not compromising the success of treatment.

Keywords: Anatomy. Bicuspid. Dental pulp cavity.
Introduction

The thorough knowledge of dental anatomy is extremely important to the success of endodontic treatment, which is composed of several interdependent steps.1,8,9,12,14,18,20 Roots and root canals can vary in number, size, shape, divisions, fusions, directions and stages of development.9 The periapical radiographs help in the study of internal anatomy and its variants,8,9 and, for better viewing, we recommend the use of two diagnostic radiographs, one orthoradial and another mesially or distally displaced.10

Often, the first premolar presents itself with two conical roots, one buccal and one palatal, and two respective canals.9,12 These roots may present themselves independent, not entirely separate or as a single root.9

However, this dental element may have many variations, especially in the amount of roots.9,12,20 The buccal root, sometimes, is divided into two: Mesio-vestibular root and distobuccal root.9,12 In this case the tooth is called “minimolar”.12 This format was described with a frequency of 2.5% by Pécora et al15 and 3.3% by Chaparro et al.4 The presence of the third canal in first premolars regardless of the number of roots was reported in 1979, by Vertucci and Gegauff,19 which examined 400 extracted teeth and found a prevalence of 5%. Recently, in 2008, Rózylo et al16 described the presence of the third canal in 9% of the cases.

Thus, the objective of this paper is to present, by means of a clinical case, a rare anatomical variation of the first premolar with three roots and three root canals, and its implications in endodontic treatment.

Case report

Male patient, 32-years-old, attended the service of endodontics, School of Dentistry of Bauru/SP, conveyed from the public health system to perform endodontic treatment of tooth #14.

Radiographically, it was observed unusual root anatomy, suggestive of two buccal roots and one palatal root (Fig 1). After performing anesthesia, access cavities and rubber dam, it was confirmed the presence of two vestibular sockets, making the final shape triangular, with a base facing the buccal aspect (Fig 2).

The exploration of the canals was performed with #10 K-file and the root canal length was measured.

by means of radiographic technique, enabling to confirm the variation in morphology and to assure that both canals were independent (Fig 3). The instrumentation was mixed, and the apical preparation was performed with K-type hand files, until #35 file; cervical and middle thirds were prepared with ProTaper® automated system (Dentsply).

Due to the presence of apical lesions, we used calcium hydroxide (Ca[OH]₂) as an intracanal medication for a month. After this period, it was performed the filling of the canal with the lateral compaction technique with Sealer 26® (Fig 4).

In the X-ray control, achieved after two years, it was observed a normal aspect of periapical region structures (Fig 5).

**Discussion**

The thorough knowledge of dental anatomy is of utmost importance for the completion of endodontic treatment, because is through this science that the dentist can estimate a three-dimensional situation of the canal system, from a two-dimensional image provided by radiographs.

Over the years, literature has reported the most varied anatomical changes of several teeth, including premolars. These variations may be related to the number of root canal, its size, shape, divisions, fusions, directions and stages of development.

Premolars are a group of teeth exclusive of the permanent dentition, and their predecessor are the first deciduous molars. They also have the basic function of crushing and grinding food, in addition to helping the speech and aesthetics. The first premolar has an average length of 21.5 mm, ranging from 17 to 25.5 mm. In most cases, they feature two conical roots — one buccal and one palatal — with one canal each one, and the vestibular root often presents a curvature towards the palatine aspect. These roots may be well developed, not entirely separate or as a single and large root, with two canals in its interior. The outline of the pulp chamber has an elliptical morphology, due to the mesiodistal flattening.

However, the amount of roots and canals can vary in this dental group, since the buccal root may divide into two, evidencing mesiovestibular and distobuccal roots. In this case, the premolar may be
referred to as a “minimolar”. According to Bellizzi and Hartwell, when this change in morphology occurs, the roots can be classified into three groups. In group 1 the three roots are merged or there is only two buccal roots, and the palatal root is semifused or free. In group 2 buccal roots present separate, from middle or apical third. In group 3 the three roots are separate from the cervical third. In this case reported, there was no certainty about the classification, since the radiographic images allow a subjective understanding on roots separation (Figs 1, 3 and 4).

Endodontic treatment of maxillary premolars with this morphology should be adjusted to such a situation, by locating all existing root canals and making the outline change from elliptical to triangular, with the base toward the buccal aspect and the apex to the lingual aspect. In the case reported, it could be seen that by making the coronal opening, due care has been taken regarding the location of the canals, which was more difficult due to the great loss of coronal structure, in particular at the distal aspect of the tooth (Fig 2).

Regarding the instrumentation employed, the use of hand files is established for confection of apical stop, and ProTaper® system consists of rotary instruments that have proven effective, improved and simplified, allowing the professional to perform more effectively and quickly the root canal treatment.

The intracanal medication has the function of eliminate remaining microorganisms and prevent recontamination, prevent or reduce periapical inflammation, solubilize organic matter, neutralize toxins, control persistent exudation, control external inflammatory resorption and stimulate repair. Calcium hydroxide is the most appropriate medication for endodontic purposes, being a substance with antimicrobial activity, inhibiting root resorption and inducing formation of hard tissue. However it is necessary a long time in contact with the tissue so that its action is successful, which justified the permanence of calcium hydroxide inside the canals for a month in this case presented.

The biological purpose of root canal filling is to provide favorable conditions for the body to repair tissue with no risk of relapse and the used calcium hydroxide-based sealer (Sealer 26®) seems to achieve this goal (Fig 4). In the case reported, the repair could be confirmed in the control radiograph, two years after completion of endodontic treatment (Fig 5).

Conclusions
Changes in shape and number of roots and root canals are likely to occur, and sometimes in a rare form, as in the premolar with three roots and three canals. Thus the professional is required to pay more attention to the diagnostic radiographs during the course of endodontic treatment, so such alterations do not affect prognosis.
